

## **Appendix A10. Breakthrough Ce/Co Plots from the Full-Depth Column Tests**

Breakthrough can be defined as a ratio of the effluent concentration (Ce) to the influent concentration (Co) that is considered unacceptable. No chemical capacity remains when  $Ce/Co \geq 1$ ; however, breakthrough can be defined at earlier times (such as by using the permit limit as Ce and calculating the ratio at which the permit limit could be expected to be exceeded). The following graphs for long-term column breakthrough tests show the Ce/Co ratios as a function of water loading on the columns. The first graph contains the data from all the media on a single graph; the second graph shows the behavior for each medium or media mixture.

The six tables at the end of this appendix compare the capacities of the various potential biofilter media components (site sand, rhyolite sand, site zeolite, SMZ, GAC, and PM) as calculated from the various testing protocols.
