## Experimental Design - Number of Samples Needed

The number of samples needed to characterize stormwater conditions for a specific site is dependent on the COV and allowable error. For most constituents and conditions, about 20 to 30 samples may be sufficient for most objectives. Most Phase 1 sites only have about 10 events, but each stratification category usually has much more.

9

Much information will be needed to confirm performance of stormwater controls for bacteria.

Obviously, easier to confirm removals when the differences between influent and effluent are greatest.

10

## Pilot-scale filters examining many different media.

### *E. coli* AND *Enterococci* REMOVAL

Significant reductions observed with relatively few pairs of observations due to high levels of reductions observed

Clark 1996 and 2000

11

## Bacteria Source Area Sampling Effort, Tuscaloosa, AL 2005 (Shergill 2004)

202 wet weather samples analyzed for *E. coli* and enterococci

- 10-12 sample pairs collected from each source area
- 176 source area samples analyzed
- Additional tests investigated effects of different sampling handling conditions (time, refrigeration, and agitation)

278 dry weather samples analyzed for *E. coli* and enterococci

- 142 reference samples (dry weather flow potential sources)
- 136 creek outfall samples analyzed

Total of 480 Samples analyzed using IDEXX methods

## Ending Comments

- Need to study bacteria sources, transport, treatment, and fate (complete mass balance) to understand relationships between receiving water uses and controls.
- Stormwater bacteria is not source limited: it frequently increases during large events, even while other constituents decrease.
- Many samples are needed to characterize bacteria levels due to very large variations.
- Urban wildlife and pets can be significant sources of indicator bacteria in urban areas: just because standards are exceeded does not mean that sewage contamination exists.
- Fate of bacteria includes traditional dieoff, but sedimentation also important. Equilibrium conditions are reached where further reductions are much slower.
- High levels of bacteria are found in urban stream sediment interstitial water.
- Bacteria analyses need to be conducted soon after the event. Samples need vigorous agitation to break up possible large colonies of bacteria before analyses. Samples should be divided using a cone splitter, as needed, before analysis.
