

9b: Biofiltration Entry and Calculation Summaries in WinSLAMM

The new data components for media types include:

- Flow rate equations based on media type, organic content, texture, and uniformity
- Regression equations for removal of several particle size ranges
- Flow rate reduction and clogging due to particulate retention
- Filterable and particulate pollutant retention
- Filterable pollutant retention based on contact time (coming)
- Breakthrough of pollutants as media retains filterable pollutants (coming)

Incorporating these data significantly expands the ability to compare alternative biofilter design options.

We will cover . . .

- **Biofilter Design Concepts and Issues**
- **Biofilter Model Algorithms**
- **Entering Biofilter Data into the Model**

The biofiltration control option uses full routing calculations associated with pond storage.

The “outlet” devices include natural soil infiltration (considering the wide range of variability in infiltration rates in urban soils), evaporation, surface discharges through overflows (a stand pipe or weirs), or through a rain barrel/cistern.

Biofiltration controls are usually numerous in an area and can be represented in the model individually or by specifying how many of each unit is treating the flow from an individual or combination of source areas.

Modeling Notes

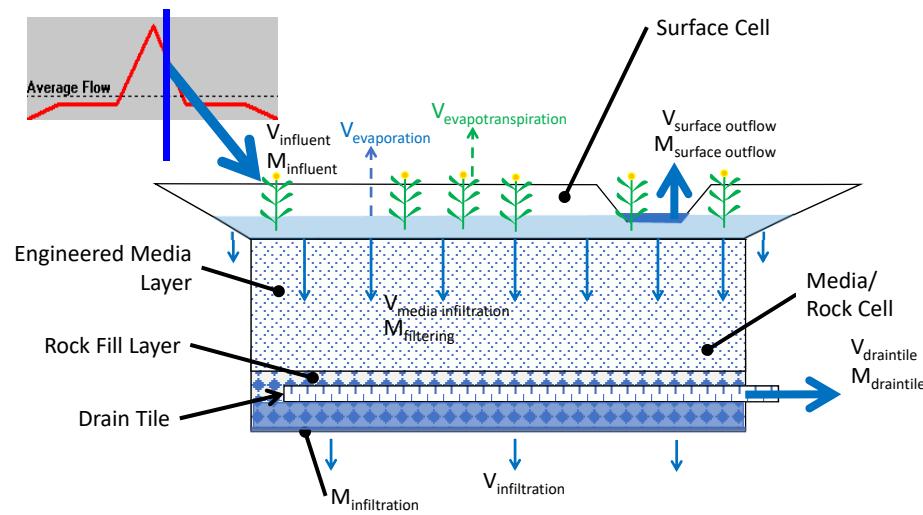

- **Biofilter routing is performed using the Modified Puls Storage – Indication Method.**
- **Time increments are established by the user**
- **Yield reductions due to:**
 - Runoff volume reduction through infiltration
 - Filtering through engineered soil

Biofilters can be used as control devices in individual source areas, in land uses, and as a part of the drainage system or at the outfall.

To model biofilters in a source area, describe the geometry and other characteristics of a typical biofilter. Then enter the number of biofilters you want to model in the source area. The model divides the runoff volume by the number of biofilters in the source area, creates a triangular hydrograph that it routes through that biofilter, and then multiplies the resulting losses by the number of biofilters to apply the results to the source area.

Biofilter Runoff and TSS Removal Processes

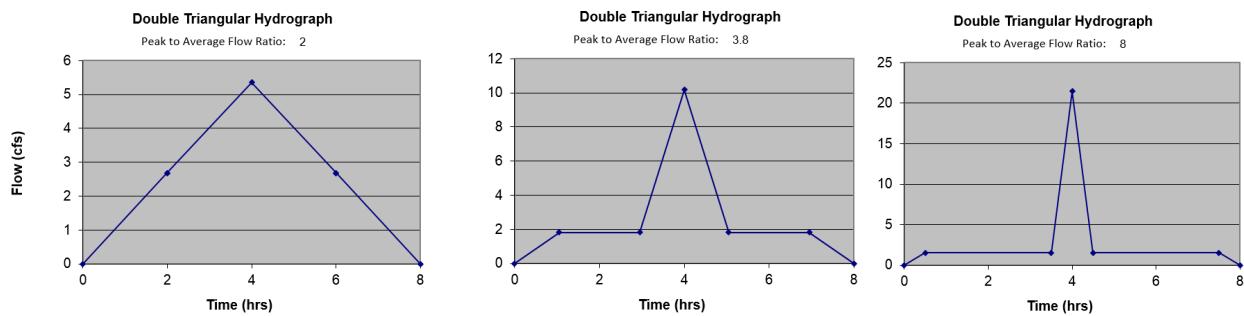

$$V_{\text{surface effluent}} = V_{\text{influent}} - V_{\text{infiltration}} - V_{\text{evapotranspiration}} - V_{\text{evaporation}} - V_{\text{surface overflow}} - V_{\text{media infiltration}}$$

$$V_{\text{media/rock cell effluent}} = V_{\text{media infiltration}} - V_{\text{infiltration}} - V_{\text{draintile}}$$

$$M_{\text{effluent}} = M_{\text{influent}} - M_{\text{filtering}} - M_{\text{infiltration}} - M_{\text{surface outflow}}$$

Biofilter Hydrograph Creation

- Flow rate calculated using Complex Triangular Hydrograph
- Runoff Volume calculated from WinSLAMM
- Runoff Duration = 1.2 times rainfall duration
- Peak to Average Flow Ratio set by user

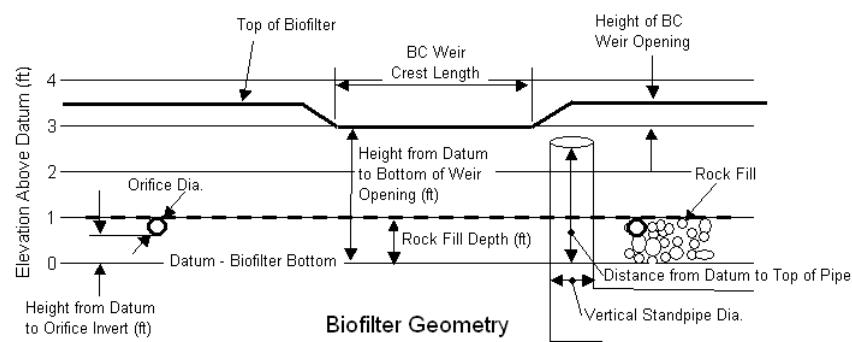

Four Components to Modeling Biofilters

1. Structure Geometry
2. Outlet Information
3. Infiltration Data
4. Hydrograph and Flow Routing Information

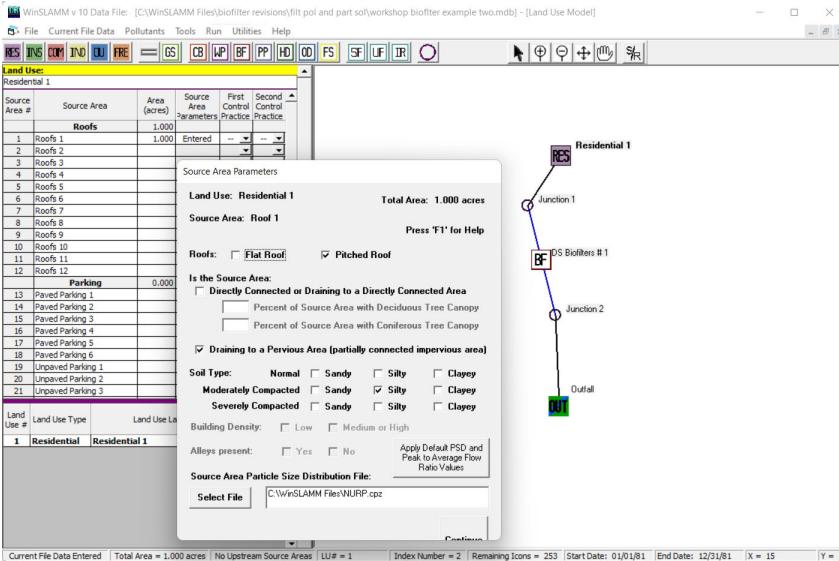

Biofilter Geometry

Biofilter Datum is always zero ft.

Basic WinSLAMM Layout and Source Area Descriptions

This is not a very reasonable design but is used in this example for its simplicity.

The example shown here is very basic for a total of 1 acre of pitched residential roofs (multiple buildings), draining to silty soils of moderate compaction).

Each control is shown on a row. Since only one biofilter in this example, only one row is shown. Different controls have different columns, depending on summary information (biofilters are the most complex).

Examples of summary tables for other data tabs

The image shows two windows of a software application. Both windows have a header with tabs: 'Land Uses', 'Junctions', 'Control Practices', 'Outfall', and 'Output Summary'. The left window is titled 'Runoff Volume (cu. ft.)' and the right window is titled 'Yield (lbs)'. Both windows show data tables with columns for Start Date, Rain Date, Total (in), Land Use Totals, Roots 1, Ry, Total Losses (in.), Calculated CN*, and various yield/concentration values.

Start Date	Rain Date	Total (in.)	Land Use Totals	Roots 1	Ry	Total Losses (in.)	Calculated CN*	Yield (lbs)	Concentration (mg/L)	Source Area Yield Contribution (%)

Selection of Optional Detailed Data in Separate Spreadsheets

The screenshot shows the 'Program Options' dialog box with several tabs: 'Program Options', 'Default Model Options', and 'Default Current File Data'. The 'Detailed Output File Options' tab is highlighted with a red border. It contains numerous checkboxes for selecting optional detailed output data for various components like Biofilters, Catchbasins, Cisterns, Filter Strips, Flow Duration Curve Data, and more. Some checkboxes are checked, such as 'Water Balance' under Biofilters and 'Evapotranspiration Detail' under Catchbasins. Other checkboxes are unchecked.

This shows the water balance optional spreadsheet selected for biofilters

Example of Detailed Data Spreadsheets for Biofilter Water Balance (1 of 2)
